Programmable Sub Micro Digital Motor Control

1.0 Features of the Pixie-20P:

- Microprocessor controlled
- Low Resistance (.0027 ohms)
- High rate (2800 Hz) switching (PWM)
- Up to 20 Amps continuous current (with proper air
- High Output (1.5amp) Battery Eliminator Circuit climinates separate receiver battery (BEC) provides power to receiver and servos -
- Five seven cells with four micro servos
- Eight cells with three micro servos
- Nine or ten cells with two micro serves
- Eighteen cells MAX with BEC disabled
- Programmable LV cutoff (none, 5.0V*, 6.0V, 7.2V
- Programmable motor cutoff hard with reset* or
- Programmable throttle range -- auto-calibrating* or fixed end points
- will not accidentally turn on Safe "power on" arming program ensures motor
- Low torque "soft start" prevents damage to fragile Auto shut down when signal is lost or radio
- Rugged surface mount construction interference becomes severe
- * Initial factory settings

Wiring Your Pixie-20P

Tools required:

Wire cutters Wire strippers (optional) Soldering Iron (25-40 watts - Do not use a soldering

Parts required:

Solder (rosin core "electronic" solder)

Battery connector

Ratings with BEC Enabled

Not Recommended	2	3	High Torque servos
2	3	4	Standard (micro) servos
9-10 cells	8 cells	5-7 cells	Servo Type

Adding the Battery Connector

wire to battery red wire, black wire to battery black wire) IS CORRECT, following the instructions for pull off the wire.) Attach the battery connector to the wires ENSURING THAT THE POLARITY (red modeling knife to carefully cut through the insulation around the wire. Then the insulation should easily to attach the battery connector. (Note: if you do not have a pair of wire strippers, you can use a to the length you require on the battery side. Strip off of the wire insulation to expose just enough wire The battery connector is attached to the side of the controller with black and red wires. Cut the wires the battery connector.

Attaching the Motor Leads

safest operation. DO NOT PLACE A FUSE IN THE CIRCUIT BETWEEN THE BATTERY AND SPEED CONTROL. YOU COULD LOSE CONTROL OF THE MODEL. the wire). There should be a '+' symbol or a RED DOT on the end of your motor which indicates which wires to the motor terminals. (Note: If you do not have a pair of wire strippers, you can use a modeling 10 amps) may be connected inline in either the white or red power wire. A fuse is recommended for the terminal must be connected to the RED wire. Connect the other terminal to the white wire. A fuse (5knife to carefully cut through the insulation around the wire. Then the insulation should easily pull off length you require on the motor side. Strip the wire insulation to expose just enough wire to solder the The motor is connected to the side of the controller with red and white wires. Cut the wires to the

Align the wires carefully and solder to the motor terminals. Ensure that all connections (battery and motor) are correctly polarized.

CONNECTING THE SPEED CONTROL. Incorrectly connecting the speed control could cause permanent damage to the controller IMPORTANT NOTE: YOU MUST BE SURE THAT ALL CONNECTIONS ARE CORRECT WHEN

Programmable Sub Micro Digital Motor Control

ALWAYS PERFORM A RANGE CHECK BEFORE FLYING WITH ANY NEW SPEED CONTROLLER! PERFORM YOUR RANGE CHECK AT FULL THROTTLE, HALF THROTTLE AND NO THROTTLE.

3.0 Flying with Your Pixie-20P:

Initialization sequence

- Connect the speed controller receiver connector to the proper channel on your receiver (usually channel 3)
- 2. Turn on your transmitter.
- 3. Connect the main power battery to the speed controller. The motor will emit a single beep.
- 4. The speed controller will remain disarmed (will not operate) until it sees more than 1 1/2 seconds of "OFF" throttle. Move the throttle arm to the lowest position on your transmitter; wait at least 1 1/2 seconds. The motor will emit two beeps when armed and the LED will flash slowly. Test the controller to make sure that the throttle operates.
- Go fly!
- 6. If the BEC cutoff occurs before you land, you may restart the motor and use low throttle if necessary by moving the throttle stick all the way down (to the off position) and then throttling back up. BEC cutoff will occur again if the voltage drops too low.

4.0 Using the Features of Your Pixie-20P

Auto-calibrating Throttle Range - The throttle range is auto-calibrated to the transmitter in use to insure maximum throttle steps.

BEC - The BEC power is supplied to the receiver and servos through the receiver connector wires. If you wish to disable the BEC and use a separate receiver battery (required for more than ten cells), you must first cut the red wire in the trio of receiver wires. Simply use a pair of wire cutters to remove a short section of the red wire near the receiver connector, and be sure to insulate the cut wire with a bit of electrical tape. Or remove the pin from the connector (pry the retaining tab up, remove the pin, and insulate the pin with electrical tape.) Then you may safely use a battery with your receiver.

Fixed Throttle Range - Fixed throttle range sets the throttle to 1.25 to 1.75 ms fixed.

Hard Cutoff – Hard motor cutoff will occur when the input battery voltage drops below the programmed voltage for more than one half second. Once motor cutoff has occurred, moving the throttle to the full off position can rearm the controller. This will allow restart of the motor at low throttle after cutoff has occurred.

WARNING! Restarting of the motor may drain the battery to the point where the radio receiver will stop operating, resulting in a loss of control of the model.

Losses of Transmitter Signal, or excessive radio noise cutoff - Motor cutoff will also occur if the signal from the transmitter is lost, or if the radio noise becomes excessive. After radio connection has been reestablished, moving the throttle to the braking position (full off) can restart the motor.

Programming Mode – The Pixie-20P is already programmed from the factory for: a) 5.0v cutoff, b) a hard cutoff with reset and c) auto calibrating throttle end points. To change any or all of these settings follow the programming instructions beginning in section 7.0.

Safe Power Up - The Safe Power up feature is a "finger saver", designed to prevent the motor from

Page 2 of 5

starting accidentally on power up. To arm the controller, the transmitter stick must be held in the "OFF" position (all the way down) for at least one and a half seconds. Until the controller is armed, it

Soft Cutoff - Soft Cutoff reduces the throttle level to keep the voltage at or near the programmed cutoff voltage level. will not provide any power to the motor, regardless of where the throttle stick on your transmitter is positioned. Before flying your model, be sure to "blip" the throttle to ensure that the controller is

0 Troubleshooting

Everything is hooked up correctly, the BEC (receiver and servos) works, but the throttle does not work.

The controller is not seeing the one and a half seconds of "dead space" (low throttle) and is not arming. The motor should emit two "beeps" when it arms. Try moving your throttle stick all the way down, and moving the trim all the way down. Wait for a couple of seconds and try the throttle again. If it still does not arm, you may need to reverse the throttle control on your transmitter (see your radio documentation). You may also check to make sure that your endpoint adjustments on your radio (if it has them) are set all the way open.

Every time I throttle all the way up, the controller "cuts off" after a few seconds, even with fresh charged batteries.

The controller will automatically shut down the motor if the battery voltage falls below programmed cutoff voltage for more than a half second. This prevents loss of control caused by low voltage at the receiver. If the cutoff is kicking in with freshly charged batteries, it means that the voltage is dropping very quickly. This is usually an indication of a motor that is drawing too much current for the batteries to handle. Try using a smaller prop on the motor, or using batteries with a higher rating (for example, if you are using 600 AE cells, you might try going to 800 AR cells.)

It is also possible that the microprocessor on the Pixie-20P is being overwhelmed by noise from the motor. This can occur if the motor has no capacitors installed. In most cases the Pixie-20P does not require capacitors to be installed on the motor. However, some motors are extremely noisy electrically, and need to have capacitors installed. If this is the case, add a capacitor across the motor terminals, or even better, add three capacitors: one across the motor terminals, and one from each terminal to the motor case. Capacitors can be purchased from Radio Shack. Be sure to get "ceramic disk" capacitors, in the range of .01uF and .1uf (.047uF being the best choice.) Do not use electrolytic (can style) or tantalum capacitors with a high-rate control.

When everything is all connected and powered on the motor emits continuous "beep"

The unit is not receiving a signal from the receiver. Make sure the receiver connector is plugged in correctly and plugged into the right channel of your receiver. Rule out the possibility of a faulty receiver.

Nothing seems to work, receiver and servos are dead, and the throttle is dead.

Check all connections to ensure that they are correct, and that the polarity (+/-) connections are correct. Ensure that the battery is not connected to the motor side of the speed controller. If everything is correctly connected, and the receiver and servos still do not work, contact the dealer where you purchased your Pixie-20P or contact Castle Creations directly. (See info below)

Programming Setting 2—Cutoff Type

Cutoff describes the way the Pixie-20P handles a low voltage situation. There are two options for cutoff type:

Option 1: Hard cutoff with restart* Recommended for aircraft use

Option 2: Soft cutoff Recommended for helicopter use

Pixie-20PTM User Guide

Page 4 of 5

By Castle Creations Programmable Sub Micro Digital Motor Control

A Hard Cutoff (the default value) will turn off the motor when a low-voltage condition occurs. Moving the throttle stick to the lowest (off) position, and then throttling back up will restart the motor. A Soft Cutoff reduces the throttle level to keep the voltage at or near the cutoff voltage level. A soft cutoff is not recommended because it is easier to accidentally run the batteries down to a point where the receiver and servos stop responding or battery damage occurs
